

Patient is a 76-year-old woman who received angioplasty procedure two years ago

However, during the procedure she suffered a mild stroke. Patient's family noticed her unusual behavior and was told belatedly about Patient's stroke. She received no rehabilitation therapy. Patient had been a very active, professional businesswoman prior to her retirement. Before starting the CSI System she would:

- Stared placidly into space with little recognition of events around her
- Seemed confused and was very forgetful due to her short-term memory loss
- Resisted going out in public
- Kept reflecting back to better times when she was able to do complicated tasks
- Unable to enjoy life, as she couldn't even remember people she had just met and spent some time with.
- After 2 ½ months of therapy, Patient's husband informed us that they were discontinuing the therapy program because he and Patient were taking a 2-month vacation that he thought they would never be able to do again. Patient herself stated, "I know I'm getting better because I feel it and can remember when I do things and how I did them." She had completed a new cognitive exercise with a high performance score, even though several people were having a conversation behind her that previously would have distracted her.
- Therapy was subsequently discontinued as patient was making good progress on her own and has been too busy to spend much time on the System.
